47 **ABSTRACT:** 48 Purpose: To evaluate childhood cancer survivors' adherence to surveillance protocols for late 49 effects of treatment and to determine the factors impacting adherence. 50 51 Methods: Between 2014-2016, 11,337 survivors and 2146 siblings in the Childhood Cancer 52 Survivor Study completed a survey ascertaining adherence to Children's Oncology Group 53 (COG) guidelines for survivors at high-risk of second malignant neoplasms (SMNs) or cardiac 54 dysfunction, and American Cancer Society (ACS) cancer screening guidelines for average risk 55 populations. Adherence rates and factors impacting adherence were analyzed. 56 57 **Results**: Median age at diagnosis was seven years (range 0-20.9) and median time from 58 diagnosis was 29 years (range 15-47). Among high-risk survivors, adherence to COG breast, 59 colorectal, skin and cardiac surveillance was 12.6% (95% confidence interval [CI] 10.0-15.3%), 60 37.0% (34.1-39.9%), 22.3% (21.2-23.4%) and 41.4% (40.1-42.7), respectively. Among average-61 risk survivors, adherence to ACS breast, cervical and colorectal screening was 57.1% (53.2-62 61.0%), 83.6% (82.7-84.5%) and 68.5% (64.7-72.2%) respectively. 27.0% of survivors and 63 20.0% of primary care providers (PCPs) had a survivor care plan (SCP). For high-risk survivors 64 SCP possession was associated with increased adherence to COG breast (22.3% vs. 8.1%, 65 prevalence ratio (PR) 2.52, CI 1.59-4.01), skin (34.8% vs. 23.0%, PR 1.16, CI 1.01-1.33), and cardiac (67.0% vs. 33.1%, PR 1.73, CI 1.55-1.92) surveillance. For high-risk survivors PCP 66 67 possession of a SCP was associated only with increased adherence to COG skin cancer surveillance (36.9% vs. 23.2%, PR 1.24, CI 1.08-1.43). 68 69 70 **Conclusion**: Guideline adherence is suboptimal. While survivor SCP possession is associated

with better adherence, few survivors and PCPs have one. New strategies to improve adherence are needed.

BACKGROUND

Of the 420,000 childhood cancer survivors in the United States,¹ many are at an elevated risk of treatment-related adverse health outcomes such as subsequent malignant neoplasms (SMN) and cardiac dysfunction^{2,3}. Adherence to risk-adapted surveillance for these outcomes can reduce mortality.^{4,5}

First published in 2003, the Children's Oncology Group (COG) Long-Term Follow-Up (LTFU) Guidelines for Survivors of Childhood, Adolescent and Young Adult Cancer⁶ recommend SMN and cardiac dysfunction surveillance in survivors at elevated risk for these morbidities. Survivors without an elevated risk are advised to adhere to the American Cancer Society (ACS) guidelines for cancer screening in the general population. A Childhood Cancer Survivor Study (CCSS) questionnaire⁸ administered between 2002-2003 demonstrated that among 8.347 survivors. 46.2%, 11.5%, 26.6% and 28.0% at high risk for breast cancer, colorectal cancer, skin cancer⁵ or cardiac dysfunction (unpublished data Dr. P. Nathan), respectively, received the recommended surveillance. Since then, numerous initiatives have aimed to improve surveillance. In 2006, the Institute of Medicine (IOM) recommended that all childhood cancer survivors receive a survivorship care plan (SCP) that documents cancer treatment-related health risks and the recommended screening and surveillance. In 2012, the American College of Surgeons Commission on Cancer made SCP provision a requirement for cancer program accreditation.¹⁰ It is now common in pediatric oncology to provide a SCP to patients and their primary care providers (PCPs) at the completion of therapy. While considerable resources have been dedicated to SCP development and distribution, it is unknown if SCPs and other educational efforts have improved guideline adherence. This study's purpose was to assess current adherence to COG and ACS cancer and cardiac surveillance guidelines, and to explore predictors of adherence. We analyzed changes in adherence between 2003 and 2016, and compared survivor

adherence to their siblings, and to general population data from the National Health Interview Survey (NHIS).

METHODS

Participants

The CCSS is a retrospective cohort study with longitudinal follow-up of five-year cancer survivors diagnosed before age 21 between 1970-1999 from 25 North American centers. ¹¹ Each site's Institutional Review Board approved the study, and participants provided consent. Eligibility for this analysis was limited to participants (n=11,337) who completed a questionnaire between 2014-2016. The CCSS has completed three trials aimed at increasing cardiac (ECHOS¹²), breast (EMPOWER¹³) and skin (ASK¹⁴) surveillance; participants were excluded from the analysis for the outcome evaluated in that study. Participants who developed a SMN or grade 3-4 (severe to life-threatening) heart failure based on the Common Terminology Criteria for Adverse Events (CTCAE) Version 4.03¹⁵ prior to questionnaire completion were excluded from the analysis for the outcome that they developed.

Cancer and cardiac surveillance in high-risk survivors

For survivors at high risk of cardiac dysfunction or breast (females only), colorectal or skin cancer, we assessed adherence to COG's LTFU Guidelines, Version 4.0 (www.survivorshipguidelines.org)⁶ published in 2013 (eTables 1 and 2). For cardiac screening, survivors were asked, "When was the last time you had an echocardiogram (ultrasound of the heart to look at the heart muscles and heart valves) or a MUGA scan?". For breast cancer, survivors were asked, "When was the last time you had a mammogram?" and "When was the last time you had a breast MRI?". Both mammogram and breast MRI were recommended, while only mammogram was recommended in the previous guidelines (Version 3.0, 2008). For

colorectal cancer, survivors were asked, "When was the last time you had a sigmoidoscopy, or colonoscopy to view the colon for signs of cancer or other problems?". For skin cancer survivors were asked "When was the last time you had a skin exam for signs of cancer by a healthcare provider?". For each investigation, participants selected "never", "less than 1 year ago", "1-2 years ago", "more than 2 but less than 5 years ago", "5 or more years ago", "I had one but I don't recall when", or "I don't know if I ever had one". For each guideline, survivors were classified as "adherent" if they completed the test within the period recommended in eTables 1 and 2.

Cancer screening in average-risk survivors

Survivors not at high-risk risk for breast or colorectal cancer are advised to adhere to ACS screening recommendations (eTable 3) for the general (average risk) population.⁷ We assessed ACS guideline adherence among survivors at average risk of developing colorectal, breast (females only) and cervical (females only) cancer. Adherence was compared to a sex-, race- and age-adjusted cohort of siblings, and to age and race matched aggregate population data from the 2015 NHIS.¹⁶ a cross-sectional survey of American health status and healthcare utilization.

Predictors of screening and surveillance

Sociodemographic data and surveillance practices were captured in the questionnaire while cancer and treatment data was extracted from medical records. SCP receipt by the survivor and PCP was reported by the survivor. Survivors were defined as not having a SCP if they answered "no" when asked, "Do you currently have a cancer survivorship care plan and/or a summary of treatment for your cancer?". PCPs were defined as not having a SCP if the survivor answered "no" or "I don't have a primary care doctor" when asked, "Does your local or primary care doctor have a copy of your cancer survivorship care plan and/or a summary of your treatment for your cancer?". Chronic health conditions were classified using the CTCAE Version 4.03. 15

Adverse health status was determined using six previously defined domains (general health, mental health, cancer-related pain, cancer-related anxiety, functional status, and activity limitations). ¹⁷⁻¹⁹ Cigarette and alcohol use were also analyzed. ^{20,21} Siblings were asked the same questions except for those addressing cancer-related pain and anxiety.

Change in adherence to breast, colorectal and cardiac surveillance over time

To assess changes in adherence to COG guidelines between questionnaires from 2002-2003, 2007-2009 and 2014-2016, survivors at high-risk of a given outcome (eTable 1 and 2) were identified at each time point. Using the COG guidelines current at the time of each questionnaire, survivors were classified as adherent to breast, colorectal and cardiac surveillance if they completed the recommended surveillance for that outcome within the recommended time. Changes in skin surveillance adherence were not assessed as prior questionnaires did not assess this outcome.

Statistical analysis

Descriptive statistics were calculated for risk group assignment, demographic, disease, and health status variables. Adherence was reported as percentages. Adherence was compared between survivors and the general population using the Wald-test. Survivors' adherence between questionnaires and to siblings was compared using a log binomial regression model. The Generalized Estimating Equation was used to account for potential within-family correlation of survivors and siblings and correlation of multiple measurements within same survivor. The prevalence ratio (PR) for adherence was estimated for each demographic and health status variable and compared in multivariable regression models. Variables with a p-value <0.2 in the univariate analysis were included in the multivariable analysis. Due to the small sample size in the high-risk breast analysis, covariates from the univariate analysis were further selected

through backward-elimination. Multivariable analysis results were used to determine predictors of adherence. Independent variable collinearity was evaluated by examining variance inflation factors and tolerance. Sampling weights were used to account for under-sampling of acute lymphoblastic leukemia survivors. Variables that were highly correlated were not included in the same model. Analysis was completed with SAS Version 9.4.

RESULTS:

Cohort characteristics

Of the 18,043 survivors in the CCSS cohort, 11,337 (62.8%; 5916 female) completed the questionnaire, along with 2146 (1245 female) siblings. Table 1 displays demographic, disease, and treatment data and eTable 4 displays health status data. Median age at primary cancer diagnosis was seven years (range 0-20.9) and time from primary diagnosis to questionnaire completion was 29 years (range 15-47). SCP possession was reported by 27% of survivors, and 20% reported PCP possession of their SCP. No differences existed in SCP possession by sex. Compared to survivors treated between 1970-1979, survivors treated between 1980-1989 (PR 1.11, 95% confidence interval [CI] 1.00-1.23, p=0.043), and 1990-1999 (PR 1.32, CI 1.16-1.49, p<0.001) were more likely to have a SCP. ECHOS¹² (n=398), ASK¹⁴ (n=728) and EMPOWER¹³ (n=162) participants were excluded from the cardiac, skin, and breast analyses respectively. Non-responders were more likely to be male, younger at diagnosis and have had leukemia (eTable 5).

Cancer and cardiac surveillance in high-risk survivors

There were 625, 1070, 5125 and 4220 survivors at high risk for developing breast cancer, colorectal cancer, skin cancer or cardiac dysfunction respectively (Table 2). Adherence to breast, colorectal, skin and cardiac surveillance was 12.64% (CI 10.0-15.3%), 37.0% (CI 34.1-39.9%),

22.3% (CI 21.2-23.4%) and 41.4% (CI 40.1-42.7) respectively (eFigure 2). In multivariable analyses, survivor-reported SCP possession was associated with increased adherence to breast (22.3% vs. 8.1%, PR 2.52, CI 1.59-4.01), skin (34.8% vs. 23.0%, PR 1.16, CI 1.01-1.33), and cardiac (67.0% vs. 33.1%, PR 1.73, CI 1.55-1.92) surveillance. PCP SCP possession was associated with increased adherence to skin surveillance (39.6% vs. 23.2%, PR 1.24, CI 1.08-1.43). Having a check-up related to past cancer in the past two years (regardless of location or provider) increased breast (PR 7.94 CI 1.99-31.74), skin (PR 1.50, CI 1.28-1.76) and cardiac (PR 1.58, CI 1.39-1.80) surveillance. Visiting a doctor more than five times in the past two years increased skin (PR 1.47, CI 1.28-1.69) and cardiac (PR 1.06, CI 0.99-1.14) surveillance. Visiting a special cancer survivorship clinic in the past 2 years increased cardiac surveillance (PR 1.16, CI 1.04-1.30) but visiting a cancer specialist did not increase adherence to any of the guidelines. There were no differences in adherence by sex. Table 3 and eTable 6 show the relationship between other factors and adherence.

Change in adherence to breast, colorectal and cardiac surveillance over time

Among high-risk survivors adherence increased from 14.3% to 41.0% (p<0.001) for colorectal and from 22.4% to 38.5% (p<0.001) for cardiac surveillance and decreased from 37.9% to 13.1% (p<0.001) for breast surveillance between 2007 and 2016 (Figure 1).

Cancer screening in average-risk survivors

There were 627, 5630 and 596 survivors at average risk for developing breast, cervical or colorectal cancer was respectively (Table 2). Adherence to ACS breast, cervical and colorectal screening was 57.1% (CI 53.2-61.0%), 83.6% (CI 82.7-84.5%) and 68.5% (CI 64.7-72.2%) respectively. In multivariable analyses, survivor SCP possession was not associated with increased adherence to breast, cervical or colorectal screening. PCP SCP possession was

associated with increased adherence to breast (PR 1.28, CI 1.13-1.45) and colorectal (PR 1.12, CI 1.04-1.21) screening. Table 4 and eTable 7 show the relationship between other factors and adherence. Compared to NHIS general population estimates, survivors were more adherent to ACS cervical (PR 1.08, CI 1.07-1.10, p<0.001), and colorectal (PR 1.15, CI 1.09-1.22, p<0.001) screening. Compared to siblings, survivors were less adherent to ACS cervical screening (PR 0.95, CI 0.93-0.97, p<0.001) (eFigure 3).

DISCUSSION

We evaluated the surveillance and screening practices of 11,337 childhood cancer survivors. In other groups at high risk of malignancy, surveillance decreases mortality^{22, 23}, and this is assumed to also be true for at-risk childhood cancer survivors. We demonstrated that less than half of high-risk survivors receive the recommended SMN and cardiac surveillance, which likely exposes them to preventable morbidity/mortality. SCPs are intended to improve adherence by providing follow-up information, and by facilitating the transition from cancer treatment to survivorship and from pediatric to adult care. Despite the IOM's recommendation⁹ and the Commission on Cancer's mandate¹⁰, few survivors and PCPs have a SCP. Survivors treated after 1990 were more likely to have a SCP suggesting that dissemination is increasing, potentially due to these recommendations. In 2017 the Commission on Cancer lowered their standard regarding the percentage of survivors that must receive a SCP from 75% to 50%¹⁰ to reflect the reality that many centers lack the resources to comply. A recent systematic review evaluating SCPs concluded that "existing research provides little evidence that SCPs improve health". ²⁴ In contrast, SCP possession by high-risk survivors in our analysis was associated with increased breast, skin, and cardiac surveillance. It is uncertain whether SCP possession leads to adherence, or whether SCP possession is a marker of a survivor who is focused on their health and thus likely to adhere to preventative health practices including surveillance.

Despite the current suboptimal adherence to COG guidelines, adherence improved between 2003 and 2016. This was most evident for colorectal (14.3% to 41.0%) and cardiac surveillance (22.4% to 38.5%). Reasons for these increases are likely multifactorial. In 2012, only 12% of general internists²⁵ and 9% of family doctors²⁶ felt at least "somewhat familiar" with care guidelines for childhood cancer survivors. Physician awareness of COG guidelines may be increasing as the time from initial publication grows. As the number of patients with SCPs increases, PCPs may be becoming more comfortable with SCPs. Survivors can receive cancer related care from PCPs or survivorship clinics. Survivorship clinics may be more familiar with guidelines and may provide additional education. In the 2 years preceding the questionnaire, 16.1% of survivors attended a survivorship clinic, but attendance only increased cardiac surveillance. Given that survivorship clinics utilize increased resource compared to PCP clinics²⁷, we must revaluate survivorship care to create cost effective programs that meaningfully impact survivors' health.

Our study did not assess barriers to obtaining surveillance tests. ECHOS¹² participants reported not obtaining echocardiograms due to a lack of time, forgetting, a perception that screening is not important, concerns about insurance and cost, and because physicians did not recommend testing. Many survivors report difficulty transitioning from pediatric to adult care.²⁸ Within the two years preceding the survey, 54.7% of survivors had a routine check-up related to their past cancer, and 92.5% had a physician visit, suggesting that survivors receive care, but that surveillance does not consistently occur at these visits. Previously identified psychosocial barriers include poor mental health, lower socioeconomic status, and lower educational level;²⁸ we identified variable effects of these factors on adherence. Skin examination adherence was particularly poor (22.3%). Belief in self-capacity to screen, fear of body shaming, fear of facing a

SMN diagnosis, and rejection of the benefit of examination may contribute to the poor uptake of skin examinations. However, given the ease of completing a skin examination, poor uptake suggests a lack of awareness of the need for surveillance, rather than concerns regarding the invasiveness, scheduling or time commitment of the investigation. Patients and PCPs may also find the recommendations overly burdensome given the high frequency of investigations required.

The CCSS has conducted three trials aimed at increasing surveillance. ECHOS showed that telephone-counseling addressing barriers to surveillance increased echocardiogram adherence. EMPOWER showed that mailed information coupled with motivational telephone interviewing increased mammography but not MRI adherence. ASK is aimed at increasing skin cancer surveillance and is ongoing. Web-based interventions have successfully altered survivor's physical activity levels and health-related quality of life, and similar platforms exist to enhance late effect awareness and surveillance. Further studies utilizing these approaches such as EMPOWER II (ClinicalTrials.gov Identifier: NCT03435380) are underway. These strategies may improve surveillance and the health of survivors; however, scaling them to the larger community of survivors, many of whom are not engaged with survivorship programs, may be difficult.

There was better adherence to ACS than to COG recommendations with 57.1%, 83.6% and 68.5% adherent to ACS breast, cervical and colorectal screening respectively. There may be greater awareness of ACS guidelines as they are population-based guidelines that PCPs utilize more regularly. We found that survivors were less adherent to breast screening than the general population, and less adherent to cervical screening than siblings. This is possibly because survivors avoid testing to escape worrying about the potential of a SMN³⁰.

Our study has several limitations. First, we used self-reported data regarding completion of surveillance and receipt of SCPs. There are no studies assessing the validity of childhood cancer survivors' self-reported screening practices. In other populations, self-reported history of cancer screening has been validated, ³¹ suggesting that the same is true for childhood cancer survivors. Many oncologists send SCPs directly to PCPs, which may result in survivors underreporting PCP's SCP possession. Second, when breast surveillance was assessed in 2003, only mammogram was recommended, whereas now both mammogram and breast MRI are recommended, making comparison of change over time difficult. Having to obtain MRIs may explain why adherence dropped by 24.9% between 2003 and 2016. Many females (35.7%) had a MRI or mammogram within the recommended period, but were classified as non-adherent. In a model of adolescent Hodgkin lymphoma survivors, breast cancer mortality at age 75 was 16.3% with mammography, and 15.4% with mammography and MRI, suggesting that having both tests may be unnecessary. Physicians may not recommend both tests if they feel that completing just one is adequate. It may also be difficult to obtain MRIs. Third, the CCSS regularly corresponds with participants, and this may increase late effect awareness and surveillance compared to the general population of survivors leading to an overestimation of adherence. Adherence may also differ between responders and non-responders (eTable 5). Fourth, survivors who participated in ASK, EMPOWER, or ECHOS were not included in the analysis for the outcome targeted in the study they participated in, but were included in the other analyses. It is possible that a "halo" effect exists, and participating in a study may increase adherence to guidelines not targeted in that study. In addition, adherence may be underestimated due to the use of strict adherence definitions. A survivor who had a test just beyond the recommended time would be classified as non-adherent, yet a short delay in testing is unlikely to adversely affect health outcomes. Finally,

Surveillance adherence in childhood cancer survivors CCSS survivors were treated in the 1970s-1990s and their health habits and adherence may not be representative of survivors treated more recently. In summary, we demonstrated that survivors at increased risk of SMNs or cardiac dysfunction report sub-optimal adherence to recommended surveillance for these outcomes. Survivor SCP possession was shown to be generally effective at increasing adherence, however few survivors have a SCP. Greater SCP awareness may improve their value. Few survivors attended specialized survivorship clinics, and attendance did not improve adherence. This data underscores the importance of improving survivorship care including increased SCP dissemination and developing and testing new interventions. Further research assessing barriers to adherence is also needed to assist in developing programs for increasing adherence.

FIGURES

Figure 1: Changes in adherence to the Children's Oncology Group's high-risk screening guidelines 2003, 2007 and 2016.

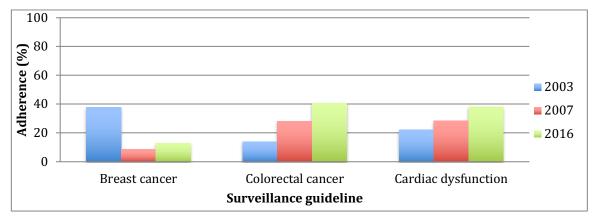

Table and Figure Captions:

Table 1: Demographic, diagnostic and treatment data of survivor and siblings

- ^a Sampling weights were used to account for under-sampling of survivors of acute lymphoblastic leukemia.
- ^b Percentages for individual characteristics calculated on total number of participants providing information for those characteristics
- ^c Survivor reports that his or her primary care doctor has their survivorship care plan or records

Table 2a: Risk group assignment of childhood cancer survivors and siblings

- ^a Sampling weights were used to account for under-sampling of survivors of acute lymphoblastic leukemia.
- ^b ECHOS participants removed from cardiac dysfunction group, EMPOWER participants removed from breast cancer group, and ASK participants removed from skin cancer group. COG and ACS group assignment are mutually exclusive. Patients in the COG risk group for an outcome were not eligible for inclusion in the ACS risk group for that outcome.
- ^c Among female survivors only n=5916
- ^d Unknown risk group as treatment data is missing

COG: Children's Oncology Group, ACS: American Cancer Society

Table 3: Multivariable analysis of predictors of adherence to COG-recommended surveillance for high-risk survivors

- ^a Variables with a p-value <0.2 in the univariate analysis were included in the multivariable analysis. For the breast cancer high-risk group analysis, due to its small number of breast cancer cases, the selected covariates by the univariate analysis were further selected by a backward-elimination variable selection in the multivariable analysisAll variables with a p-value <0.20 in the univariate analysis were included in the multivariable analysis. Independent variable collinearity was evaluated by examining variance inflation factors and tolerance. Variables that were highly correlated were not included in the same models. The multivariable analysis of colorectal cancer, skin cancer and cardiac dysfunction is adjusted for sex, race, and age at questionnaire and age at diagnosis. The multivariable analysis of breast cancer surveillance is adjusted for race, age at questionnaire and age at diagnosis.
- ^b Sampling weights were used to account for under-sampling of survivors of acute lymphoblastic leukemia.
- ^c Breast cancer adherence defined as completing both mammography and breast MRI within the recommended period. In the general population, breast cancer screening was optional for women aged 40-44 so these women were excluded from this analysis.
- ^d Denotes statistical significance
- ^e Survivor reports that his or her primary care doctor has their survivorship care plan or records Ref: Reference, MRI: Magnetic Resonance Imaging, CNS: Central Nervous System, HL: Hodgkin Lymphoma, NHL: Non-Hodgkin Lymphoma

Table 4: Multivariable analysis of predictors of adherence to ACS recommended screening for average-risk survivors

- ^a Sampling weights were used to account for under-sampling of survivors of acute lymphoblastic leukemia.
- ^bAll variables with a p-value <0.20 in the univariate analysis were included in the multivariable analysis.

 Independent variable collinearity was evaluated by examining variance inflation factors and tolerance. Variables that were highly correlated were not included in the same models. The multivariable analysis of colorectal cancer, skin cancer and cardiac dysfunction is adjusted for sex, race, age at questionnaire and age at diagnosis. The multivariable

analysis of breast cancer surveillance adjusted for race, age at questionnaire and age at diagnosis.

- ^c Denotes statistical significance
- ^d No eligible survivors age 0-4 screened for colon cancer so 5-9 used as reference age.
- ^e No eligible survivors
- ^f Survivor reports that his or her primary care doctor has their survivorship care plan or records

Ref: Reference, CNS: Central Nervous System, HL: Hodgkin Lymphoma, NHL: Non-Hodgkin Lymphoma

Figure 1: Changes in adherence to the Children's Oncology Group's high-risk screening guidelines 2003, 2007 and 2016.

- ^a When breast cancer screening was assessed in 2003, 2007 and 2016 their were n=311, n=339, and n=382 eligible survivors at each time point respectively. In 2003, 2007 and 2016, n=118, n=29 and n=50 survivors were adherent to breast cancer screening. Between 2013 and 2016 adherence statistically decreased p<0.001.
- ^b When colorectal cancer screening was assessed in 2003, 2007 and 2016 their were n=468, n=663, and n=886 eligible survivors at each time point respectively. In 2003, 2007 and 2016, n=67, n=189 and n=363 survivors were adherent to breast cancer screening. Between 2013 and 2016 adherence statistically increased p<0.001.
- ^c When cardiac dysfunction screening was assessed in 2003, 2007 and 2016 their were n=1386, n=1478, and n=1545 eligible survivors at each time point respectively. In 2003, 2007 and 2016, n=310, n=423 and n=594 survivors were adherent to cardiac dysfunction screening. Between 2013 and 2016 adherence statistically increased p<0.001.

Author Contributions:

Adam P. Yan contributed to the conception and design of the study, contributed to the analysis and interpretation of data, and drafted the manuscript. Yan Chen and Yutaka Yasui provided statistical support and critically reviewed the manuscript. Tara O. Henderson, Kevin C. Oeffinger, Melissa M. Hudson, Todd M. Gibson, Joseph P. Neglia, Wendy M. Leisenring, Kirsten K. Ness, Jennifer S. Ford, Leslie L. Robison and Gregory T. Armstrong contributed to the conception and design of the study and critically reviewed the manuscript. Paul C. Nathan was the senior author who contributed to the conception and design of the study, contributed to data interpretation, and critically reviewed the manuscript.
